DECEMBER 2025

PIONEERING THE QUANTUM-SECURE ERA OF STABLECOINS

ETHEREUM'S SECURITY IS RUNNING OUT OF TIME

The quantum threat is growing exponentially, with advancements in qubit scalability and error correction accelerating progress. Breakthroughs like Google's Willow chip, achieved faster than experts predicted, demonstrate the rapid pace of quantum computing development.

As quantum computers advance, Ethereum's traditional cryptography will face unprecedented risks. Built to withstand classical computing, this cryptography is no match for quantum machines, which could crack wallets within minutes.

QUANTUM COMPUTING: A MODERN MANHATTAN PROJECT

Would you disclose groundbreaking advancements if trillions of dollars were at stake, knowing it could leave others vulnerable? The race for quantum computing dominance has become a high-stakes geopolitical arms race. History demonstrates that secrecy often shields the powerful while exposing the public to immense risks. What if quantum breakthroughs are already here, concealed by governments or corporations?

1940s	1970s-1980s	1970s-1980s	2020s
Manhattan Project The U.S. secretly developed nuclear weapons during WWII, reshaping global power while denying adversaries a counter-strategy.	Stealth Fighter Development The U.S. kept radar-evading technology classified, ensuring a military edge over adversaries unaware of stealth capabilities.	AI Military Project Military-grade AI advancements, including autonomous drones, were classified, preventing competitors from preparing for emerging threats.	Quantum Computing Quantum advancements are likely concealed, leaving the public unprepared for transformative changes.

ETHEREUM & STABLECOINS ARE NOT READY

Despite progress, Ethereum's roadmap still defers quantum resistance to "The Splurge," its distant final phase. The Ethereum Foundation remains slow to implement major changes, often stalled by conflicting stakeholder interests, and stablecoin issuers built on Ethereum share the vulnerabilities.

Despite progress, Ethereum's roadmap still defers quantum resistance to "The Splurge," its distant final phase. The Ethereum Foundation remains slow to implement major changes, often stalled by conflicting stakeholder interests, and stablecoin issuers built on Ethereum share the vulnerabilities.

The National Institute of Standards and Technology (NIST) has stated that by 2030, the ECDSA encryption standard will be deprecated and fully banned by 2035 highlighting how close the quantum-safe transition really is.

MOSCA'S THEOREM

MOSCA'S THEOREM APPLIED TO BLOCKCHAIN

X (Data Security Needs):

How long do you need encryption to be secure?

Y (Transition Time):

How much time will it take to re-tool the existing infrastructure with large-scale quantum-safe solutions?

Z (Quantum Development):

How long will it take for a large-scale quantum computer to be built (highly unpredictable)?

Theorem: If $x + y > z$, then worry.

We act on the **Y**

INTRODUCING

S U V A

QUANTUM PROOF STABLECOIN PROTOCOL

THE SUVA SIGNING PROTOCOL

Suva Wallet leverages ERC-4337, utilizing smart contract wallets to implement custom cryptographic algorithms. This replaces Ethereum's default quantum-vulnerable cryptography with quantum-resistant alternatives for transaction verification.

Smart contract wallets also offer additional benefits, such as enabling gas fee payments with non-native assets and supporting full chain agnosticism, allowing seamless functionality across all EVM-compatible chains.

COLLATERALISE TO PROTECT

SuVa upgrades existing quantum-insecure stablecoins on the Ethereum blockchain into quantum-secured, fully collateralised assets ready for global financial applications.

QUANTUM PROOF STABLECOIN PROTOCOL

With SuVa, your transactions are protected using two keys: a standard blockchain key (EVM Key) and a quantum-secure key for added security. These keys work together in a Quantum Secure Environment to make your transactions resistant to future quantum computing threats, ensuring your assets stay safe.

SPHINCS+ EVM

SPHINCS+, the NIST-recognized gold standard for post-quantum cryptography, has been optimized by us into SPHINCS+ EVM—an audited, proprietary solution uniquely designed to significantly reduce gas costs while preserving its proven quantum resistance. This innovation replaces the obsolete, quantum-vulnerable ECDSA, offering a level of security that quantum computers cannot break.

WHY NOW?

Over the past six years, content related to blockchain quantum vulnerabilities has shown consistent growth, reflecting growing awareness of this critical issue. In the past year, this trend surged dramatically, with a staggering spike last quarter—possibly foreshadowing quantum security as the next big meta.

QoQ Growth

24.83%

YoY Growth

15.00%

THIS ISN'T THE FUTURE OF DEFI IT'S THE FUTURE OF FINANCE

Quantum computing will not only disrupt blockchains, it will compromise traditional banking infrastructure. From payment processors to interbank authentication, the world's financial system still relies on encryption standards that quantum computers can break. SuVa's post-quantum stablecoin architecture provides the secure backbone for a new era of finance.

MARKET OPPORTUNITY

Stablecoins are projected to grow to a \$1.2 trillion market by 2028, according to a new report by Coinbase analysts.

Stablecoin transaction volumes exceeded \$27 trillion per year, processing \$100 billion daily.

Stablecoins could soon outscale major cryptocurrencies and traditional payment systems. As major institutions enter and adoption accelerates, they will demand quantum-safe, secure infrastructure, unwilling to rely on insecure rails.

\$SVA TOKEN ALLOCATION: BUILDING A SUSTAINABLE ECOSYSTEM

THANK YOU
